## Chapter 7

## Covering Maps

Chapters 3-6 have focused on positive results; now we will turn our attention to techniques that can be used to prove negative results. We will start with so-called covering maps-we will use covering maps to prove that many problems cannot be solved at all with deterministic PN -algorithms.

### 7.1 Definition

A covering map is a topological concept that finds applications in many areas of mathematics, including graph theory. We will focus on one special case: covering maps between port-numbered networks.

Let $N=(V, P, p)$ and $N^{\prime}=\left(V^{\prime}, P^{\prime}, p^{\prime}\right)$ be port-numbered networks, and let $\phi: V \rightarrow V^{\prime}$. We say that $\phi$ is a covering map from $N$ to $N^{\prime}$ if the following holds:
(a) $\phi$ is a surjection: $\phi(V)=V^{\prime}$.
(b) $\phi$ preserves degrees: $\operatorname{deg}_{N}(v)=\operatorname{deg}_{N^{\prime}}(\phi(v))$ for all $v \in V$.
(c) $\phi$ preserves connections and port numbers: $p(u, i)=(v, j)$ implies $p^{\prime}(\phi(u), i)=(\phi(v), j)$.

See Figures 7.1-7.3 for examples.
We can also consider labeled networks, for example, networks with local inputs. Let $f: V \rightarrow X$ and $f^{\prime}: V^{\prime} \rightarrow X$. We say that $\phi$ is a covering

Figure 7.1: There is a covering map $\phi$ from $N$ to $N^{\prime}$ that maps $a_{i} \mapsto a$, $b_{i} \mapsto b, c_{i} \mapsto c$, and $d_{i} \mapsto d$ for each $i \in\{1,2\}$.

Figure 7.2: There is a covering map $\phi$ from $N$ to $N^{\prime}$ that maps $v_{i} \mapsto v$ for each $i \in\{1,2,3\}$. Here $N$ is a simple port-numbered network but $N^{\prime}$ is not.

Figure 7.3: There is a covering map $\phi$ from $N$ to $N^{\prime}$ that maps $v_{i} \mapsto v$ for each $i \in\{1,2\}$. Again, $N$ is a simple port-numbered network but $N^{\prime}$ is not.
map from $(N, f)$ to $\left(N^{\prime}, f^{\prime}\right)$ if $\phi$ is a covering map from $N$ to $N^{\prime}$ and the following holds:
(d) $\phi$ preserves labels: $f(v)=f^{\prime}(\phi(v))$ for all $v \in V$.

### 7.2 Covers and Executions

Now we will study covering maps from the perspective of deterministic PN -algorithms. The basic idea is that a covering map $\phi$ from $N$ to $N^{\prime}$ fools any PN -algorithm $A$ : a node $v$ in $N$ is indistinguishable from the node $\phi(v)$ in $N^{\prime}$.

Without further ado, we state the main result and prove it-many applications and examples will follow.

Theorem 7.1. Assume that
(a) A is a deterministic PN -algorithm with $X=$ Input $_{A}$,
(b) $N=(V, P, p)$ and $N^{\prime}=\left(V^{\prime}, P^{\prime}, p^{\prime}\right)$ are port-numbered networks,
(c) $f: V \rightarrow X$ and $f^{\prime}: V^{\prime} \rightarrow X$ are arbitrary functions, and
(d) $\phi: V \rightarrow V^{\prime}$ is a covering map from $(N, f)$ to $\left(N^{\prime}, f^{\prime}\right)$.

Let
(e) $x_{0}, x_{1}, \ldots$ be the execution of $A$ on $(N, f)$, and
(f) $x_{0}^{\prime}, x_{1}^{\prime}, \ldots$ be the execution of $A$ on $\left(N^{\prime}, f^{\prime}\right)$.

Then for each $t=0,1, \ldots$ and each $v \in V$ we have $x_{t}(v)=x_{t}^{\prime}(\phi(v))$.
Proof. We will use the notation of Section 3.3.2; the symbols with a prime refer to the execution of $A$ on $\left(N^{\prime}, f^{\prime}\right)$. In particular, $m_{t}^{\prime}\left(u^{\prime}, i\right)$ is the message received by $u^{\prime} \in V^{\prime}$ from port $i$ in round $t$ in the execution of $A$ on $\left(N^{\prime}, f^{\prime}\right)$, and $m_{t}^{\prime}\left(u^{\prime}\right)$ is the vector of messages received by $u^{\prime}$.

The proof is by induction on $t$. To prove the base case $t=0$, let $v \in V, d=\operatorname{deg}_{N}(v)$, and $v^{\prime}=\phi(v)$; we have

$$
x_{0}^{\prime}\left(v^{\prime}\right)=\operatorname{init}_{A, d}\left(f^{\prime}\left(v^{\prime}\right)\right)=\operatorname{init}_{A, d}(f(v))=x_{0}(v) .
$$

For the inductive step, let $(u, i) \in P,(v, j)=p(u, i), d=\operatorname{deg}_{N}(u)$, $\ell=\operatorname{deg}_{N}(v), u^{\prime}=\phi(u)$, and $v^{\prime}=\phi(v)$. Let us first consider the messages sent by $v$ and $v^{\prime}$; by the inductive assumption, these are equal:

$$
\operatorname{send}_{A, \ell}\left(x_{t-1}^{\prime}\left(v^{\prime}\right)\right)=\operatorname{send}_{A, \ell}\left(x_{t-1}(v)\right)
$$

A covering map $\phi$ preserves connections and port numbers: $(u, i)=$ $p(v, j)$ implies $\left(u^{\prime}, i\right)=p^{\prime}\left(v^{\prime}, j\right)$. Hence $m_{t}(u, i)$ is component $j$ of $\operatorname{send}_{A, \ell}\left(x_{t-1}(v)\right)$, and $m_{t}^{\prime}\left(u^{\prime}, i\right)$ is component $j$ of $\operatorname{send}_{A, \ell}\left(x_{t-1}^{\prime}\left(v^{\prime}\right)\right)$. It follows that $m_{t}(u, i)=m_{t}^{\prime}\left(u^{\prime}, i\right)$ and $m_{t}(u)=m_{t}^{\prime}\left(u^{\prime}\right)$. Therefore

$$
\begin{aligned}
x_{t}^{\prime}\left(u^{\prime}\right) & =\operatorname{receive}_{A, d}\left(x_{t-1}^{\prime}\left(u^{\prime}\right), m_{t}^{\prime}\left(u^{\prime}\right)\right) \\
& =\operatorname{receive}_{A, d}\left(x_{t-1}(u), m_{t}(u)\right)=x_{t}(u)
\end{aligned}
$$

In particular, if the execution of $A$ on $(N, f)$ stops in time $T$, the execution of $A$ on $\left(N^{\prime}, f^{\prime}\right)$ stops in time $T$ as well, and vice versa. Moreover, $\phi$ preserves the local outputs: $x_{T}(v)=x_{T}^{\prime}(\phi(v))$ for all $v \in V$.

### 7.3 Examples

We will give representative examples of negative results that we can easily derive from Theorem 7.1. First, we will observe that a deterministic PN-algorithm cannot break symmetry in a cycle-unless we provide some symmetry-breaking information in local inputs.

Lemma 7.2. Let $G=(V, E)$ be a cycle graph, let $A$ be a deterministic PN -algorithm, and let $f$ be a constant function $f: V \rightarrow\{0\}$. Then there is a simple port-numbered network $N=(V, P, p)$ such that
(a) the underlying graph of $N$ is $G$, and
(b) if A stops on $(N, f)$, the output is a constant function $g: V \rightarrow\{c\}$ for some $c$.

Proof. Label the nodes $V=\left\{v_{1}, v_{2}, \ldots, v_{n}\right\}$ along the cycle so that the edges are

$$
E=\left\{\left\{v_{1}, v_{2}\right\},\left\{v_{2}, v_{3}\right\}, \ldots,\left\{v_{n-1}, v_{n}\right\},\left\{v_{n}, v_{1}\right\}\right\}
$$

Choose the port numbering $p$ as follows:

$$
\begin{aligned}
p: & \left(v_{1}, 1\right) \mapsto\left(v_{2}, 2\right),\left(v_{2}, 1\right) \mapsto\left(v_{3}, 2\right), \ldots, \\
& \left(v_{n-1}, 1\right) \mapsto\left(v_{n}, 2\right),\left(v_{n}, 1\right) \mapsto\left(v_{1}, 2\right) .
\end{aligned}
$$

See Figure 7.2 for an illustration in the case $n=3$.
Define another port-numbered network $N^{\prime}=\left(V^{\prime}, P^{\prime}, p^{\prime}\right)$ with $V^{\prime}=$ $\{v\}, P^{\prime}=\{(v, 1),(v, 2)\}$, and $p(v, 1)=(v, 2)$. Let $f^{\prime}: V^{\prime} \rightarrow\{0\}$. Define a function $\phi: V \rightarrow V^{\prime}$ by setting $\phi\left(v_{i}\right)=v$ for each $i$.

Now we can verify that $\phi$ is a covering map from $(N, f)$ to $\left(N^{\prime}, f^{\prime}\right)$. Assume that $A$ stops on ( $N, f$ ) and produces an output $g$. By Theorem 7.1, $A$ also stops on ( $N^{\prime}, f^{\prime}$ ) and produces an output $g^{\prime}$. Let $c=g^{\prime}(\nu)$. Now

$$
g\left(v_{i}\right)=g^{\prime}\left(\phi\left(v_{i}\right)\right)=g^{\prime}(v)=c
$$

for all $i$.
In the above proof, we never assumed that the execution of $A$ on $N^{\prime}$ makes any sense-after all, $N^{\prime}$ is not even a simple port-numbered network, and there is no underlying graph. Algorithm $A$ was never designed to be applied to such a strange network with only one node. Nevertheless, the execution of $A$ on $N^{\prime}$ is formally well-defined, and Theorem 7.1 holds. We do not really care what $A$ outputs on $N^{\prime}$, but the existence of a covering map can be used to prove that the output of $A$ on $N$ has certain properties. It may be best to interpret the execution of $A$ on $N^{\prime}$ as a thought experiment, not as something that we would actually try to do in practice.

Lemma 7.2 has many immediate corollaries.
Corollary 7.3. Let $\mathscr{F}$ be the family of cycle graphs. Then there is no deterministic PN -algorithm that solves any of the following problems on $\mathscr{F}$ :
(a) maximal independent set,
(b) 1.999-approximation of a minimum vertex cover,
(c) 2.999-approximation of a minimum dominating set,
(d) maximal matching,
(e) vertex coloring,
(f) weak coloring,
(g) edge coloring.

Proof. In each of these cases, there is a graph $G \in \mathscr{F}$ such that a constant function is not a feasible solution in the network $N$ that we constructed in Lemma 7.2.

For example, consider the case of dominating sets; other cases are similar. Assume that $G=(V, E)$ is a cycle with $3 k$ nodes. Then a minimum dominating set consists of $k$ nodes-it is sufficient to take every third node. Hence a 2.999-approximation of a minimum dominating set consists of at most $2.999 k<3 k$ nodes. A solution $D=V$ violates the approximation guarantee, as $D$ has too many nodes, while $D=\varnothing$ is not a dominating set. Hence if $A$ outputs a constant function, it cannot produce a 2.999 -approximation of a minimum dominating set.

Lemma 7.4. There is no deterministic PN -algorithm that finds a weak coloring for every 3-regular graph.

Proof. Again, we are going to apply the standard technique: pick a suitable 3-regular graph $G$, find a port-numbered network $N$ that has $G$ as its underlying graph, find a smaller network $N^{\prime}$ such that we have a covering map $\phi$ from $N$ to $N^{\prime}$, and apply Theorem 7.1.

However, it is not immediately obvious which 3-regular graph would be appropriate; hence we try the simplest possible case first. Let $G=$ ( $V, E$ ) be the complete graph on four nodes: $V=\{s, t, u, v\}$, and we have an edge between any pair of nodes; see Figure 7.4. The graph is certainly 3-regular: each node is adjacent to the other three nodes.

Now it is easy to verify that the edges of $G$ can be partitioned into a 2 -factor $X$ and a 1 -factor $Y$. The 2 -factor consists of a cycle and a 1 -factor consists of disjoint edges. We can use the factors to guide the selection of port numbers in $N$.

In the cycle induced by $X$, we can choose symmetric port numbers using the same idea as what we had in the proof of Lemma 7.2; one end of each edge is connected to port 1 while the other end is connected to

Figure 7.4: Graph $G$ is the complete graph on four nodes. The edges of $G$ can be partitioned into a 2 -factor $X$ and a 1-factor $Y$. Network $N$ has $G$ as its underlying graph, and there is a covering map $\phi$ from $N$ to $N^{\prime}$
port 2. For the edges of the 1 -factor $Y$, we can assign port number 3 at each end. We have constructed the port-numbered network $N$ that is illustrated in Figure 7.4.

Now we can verify that there is a covering map $\phi$ from $N$ to $N^{\prime}$, where $N^{\prime}$ is the network with one node illustrated in Figure 7.4. Therefore in any algorithm $A$, if we do not have any local inputs, all nodes of $N$ will produce the same output. However, a constant output is not a weak coloring of $G$.

In the above proof, we could have also partitioned the edges of $G$ into three 1 -factors, and we could have used the 1 -factorization to guide the selection of port numbers. However, the above technique is more general: there are 3-regular graphs that do not admit a 1 -factorization but that can be partitioned into a 1 -factor and a 2 -factor.

So far we have used only one covering map in our proofs; the following lemma gives an example of the use of more than one covering map.

Lemma 7.5. Let $\mathscr{F}=\left\{G_{3}, G_{4}\right\}$, where $G_{3}$ is the cycle graph with 3 nodes, and $G_{4}$ is the cycle graph with 4 nodes. There is no deterministic PNalgorithm that solves the following problem $\Pi$ on $\mathscr{F}$ : in $\Pi\left(G_{3}\right)$ all nodes output 3 and in $\Pi\left(G_{4}\right)$ all nodes output 4.

Proof. We again apply the construction of Lemma 7.2; for each $i \in$ $\{3,4\}$, let $N_{i}$ be the symmetric port-numbered network that has $G_{i}$ as the underlying graph.

Now it would be convenient if we could construct a covering map from $N_{4}$ to $N_{3}$; however, this is not possible (see the exercises). Therefore we proceed as follows. Construct a one-node network $N^{\prime}$ as in the proof of Lemma 7.2, construct the covering map $\phi_{3}$ from $N_{3}$ to $N^{\prime}$, and construct the covering map $\phi_{4}$ from $N_{4}$ to $N^{\prime}$; see Figure 7.5. The local inputs are assumed to be all zeros.

Let $A$ be a PN -algorithm, and let $c$ be the output of the only node of $N^{\prime}$. If we apply Theorem 7.1 to $\phi_{3}$, we conclude that all nodes of $N_{3}$ output $c$; if $A$ solves $\Pi$ on $G_{3}$, we must have $c=3$. However, if we apply

Figure 7.5: The structure of the proof of Lemma 7.5.

Theorem 7.1 to $\phi_{4}$, we learn that all nodes of $N_{4}$ also output $c=3$, and hence $A$ cannot solve $\Pi$ on $\mathscr{F}$.

We have learned that a deterministic PN -algorithm cannot determine the length of a cycle. In particular, a deterministic PN-algorithm cannot determine if the underlying graph is bipartite.

### 7.4 Quiz

Let $G=(V, E)$ be a graph. A set $X \subseteq V$ is a $k$-tuple dominating set if for every $v \in V$ we have $\left|\operatorname{ball}_{G}(v, 1) \cap X\right| \geq k$. Consider the problem of finding a minimum 2 -tuple dominating set in cycles. What is the best (i.e. smallest) approximation ratio we can achieve in the PN model?

### 7.5 Exercises

We use the following definition in the exercises. A graph $G$ is homogeneous if there are port-numbered networks $N$ and $N^{\prime}$ and a covering map $\phi$ from $N$ to $N^{\prime}$ such that $N$ is simple, the underlying graph of $N$ is
$G$, and $N^{\prime}$ has only one node. For example, Lemma 7.2 shows that all cycle graphs are homogeneous.

Exercise 7.1 (finding port numbers). Consider the graph $G$ and network $N^{\prime}$ illustrated in Figure 7.6. Find a simple port-numbered network $N$ such that $N$ has $G$ as the underlying graph and there is a covering map from $N$ to $N^{\prime}$.

Exercise 7.2 (homogeneity). Assume that $G$ is homogeneous and it contains a node of degree at least two. Give several examples of graph problems that cannot be solved with any deterministic PN-algorithm in any family of graphs that contains $G$.

Exercise 7.3 (regular and homogeneous). Show that the following graphs are homogeneous:
(a) graph $G$ illustrated in Figure 7.7,
(b) graph $G$ illustrated in Figure 7.6.

$$
\triangleright \text { hint } A
$$

Exercise 7.4 (complete graphs). Recall that we say that a graph $G=$ $(V, E)$ is complete if for all nodes $u, v \in V, u \neq v$, there is an edge $\{u, v\} \in E$. Show that
(a) any $2 k$-regular graph is homogeneous,
(b) any complete graph with $2 k$ nodes has a 1 -factorization,
(c) any complete graph is homogeneous.

Exercise 7.5 (dominating sets). Let $\Delta \in\{2,3, \ldots\}$, let $\epsilon>0$, and let $\mathscr{F}$ consist of all graphs of maximum degree at most $\Delta$. Show that it is possible to find a $(\Delta+1)$-approximation of a minimum dominating set in constant time in family $\mathscr{F}$ with a deterministic PN-algorithm. Show that it is not possible to find a $(\Delta+1-\epsilon)$-approximation with a deterministic PN -algorithm.

Figure 7.6: Graph $G$ and network $N^{\prime}$ for Exercises 7.1 and 7.3b.

Figure 7.7: Graph $G$ for Exercise 7.3a.

Figure 7.8: Graph $G$ for Exercise 7.7.

Exercise 7.6 (covers with covers). What is the connection between covering maps and the vertex cover 3-approximation algorithm in Section 3.6?

* Exercise 7.7 (3-regular and not homogeneous). Consider the graph $G$ illustrated in Figure 7.8.
(a) Show that $G$ is not homogeneous.
(b) Present a deterministic PN -algorithm $A$ with the following property: if $N$ is a simple port-numbered network that has $G$ as the underlying graph, and we execute $A$ on $N$, then $A$ stops and produces an output where at least one node outputs 0 and at least one node outputs 1.
(c) Find a simple port-numbered network $N$ that has $G$ as the underlying graph, a port-numbered network $N^{\prime}$, and a covering map $\phi$ from $N$ to $N^{\prime}$ such that $N^{\prime}$ has the smallest possible number of nodes.

$\triangle$ hint $C$

* Exercise 7.8 (covers and connectivity). Assume that $N=(V, P, p)$ and $N^{\prime}=\left(V^{\prime}, P^{\prime}, p^{\prime}\right)$ are simple port-numbered networks such that there is a covering map $\phi$ from $N$ to $N^{\prime}$. Let $G$ be the underlying graph of network $N$, and let $G^{\prime}$ be the underlying graph of network $N^{\prime}$.
(a) Is it possible that $G$ is connected and $G^{\prime}$ is not connected?
(b) Is it possible that $G$ is not connected and $G^{\prime}$ is connected?
* Exercise 7.9 ( $k$-fold covers). Let $N=(V, P, p)$ and $N^{\prime}=\left(V^{\prime}, P^{\prime}, p^{\prime}\right)$ be simple port-numbered networks such that the underlying graphs of $N$ and $N^{\prime}$ are connected, and assume that $\phi: V \rightarrow V^{\prime}$ is a covering map from $N$ to $N^{\prime}$. Prove that there exists a positive integer $k$ such that the following holds: $|V|=k\left|V^{\prime}\right|$ and for each node $v^{\prime} \in V^{\prime}$ we have $\left|\phi^{-1}\left(v^{\prime}\right)\right|=k$. Show that the claim does not necessarily hold if the underlying graphs are not connected.

### 7.6 Bibliographic Notes

The use of covering maps in the context of distributed algorithm was introduced by Angluin [1]. The general idea of Exercise 7.7 can be traced back to Yamashita and Kameda [5], while the specific construction in Figure 7.8 is from Bondy and Murty's textbook [3, Figure 5.10]. Parts of exercises 7.1, 7.3, 7.4, and 7.5 are inspired by our work [2,4].
