# Models of distributed computing: port numbering and local algorithms 

## Jukka Suomela

Adaptive Computing Group

Helsinki Institute for Information Technology HIIT
University of Helsinki
FMT seminar, 26 February 2010

## Our research focus

- Very restrictive models of distributed computing
- Local algorithms (constant-time distributed algorithms)
- Algorithms in anonymous networks
- Deterministic algorithms
- Graph problems
- Vertex covers, dominating sets, ...
- Linear programs in graphs
- Approximability

## Outline of today's talk

- Models of computation
- Local algorithms
- Port-numbering model
- Observations and results
- What is known about these models?
- Case study: vertex cover problem
- Connections to other models of computation
- Constant-depth bounded-fan-in circuits, $\mathrm{NC}^{0}$

## Part I: Models of computation

- Distributed algorithms in general
- Two very limited special cases:
- Local algorithms
- Port-numbering model

## Distributed algorithms

- Communication graph $G$

- Node = computer
- e.g., Turing machine, finite state machine
- Edge = communication link
- computers can exchange messages

## Distributed algorithms

- All nodes are identical, run the same algorithm
- We can choose the algorithm
- An adversary chooses the structure of $G$
- Our algorithm must produce a correct output in any graph $G$

## Distributed algorithms

- Usually, computational problems are related to the structure of the communication graph $G$
- Example: find a maximal independent set for $G$
- The same graph is both the input and the system that tries to solve the problem...

## Synchronous distributed algorithms

## 1. Each node reads its own local input

- Depends on the problem, for example:
- node identifier
- node weight
- weights of incident edges
- May be empty

## Synchronous distributed algorithms

1. Each node reads its own local input
2. Repeat synchronous communication rounds

## Synchronous distributed algorithms

1. Each node reads its own local input
2. Repeat synchronous communication rounds until all nodes have announced their local outputs

- Solution of the problem

## Synchronous distributed algorithms

1. Each node reads its own local input
2. Repeat synchronous communication rounds until all nodes have announced their local outputs

Example: Find a maximal independent set /
Local output of a node $v$ indicates whether $v \in I$

## Synchronous distributed algorithms

- Communication round: each node

1. sends a message to each neighbour

## Synchronous distributed algorithms

- Communication round: each node

1. sends a message to each neighbour
(message propagation...)

## Synchronous distributed algorithms

- Communication round: each node

1. sends a message to each neighbour
2. receives a message from each neighbour

## Synchronous distributed algorithms

- Communication round: each node

1. sends a message to each neighbour
2. receives a message from each neighbour
3. updates its own state

## Synchronous distributed algorithms

- Communication round: each node

1. sends a message to each neighbour
2. receives a message from each neighbour
3. updates its own state
4. possibly stops and announces its output

## Synchronous distributed algorithms

- Communication rounds are repeated until all nodes have stopped and announced their outputs
- Running time = number of rounds
- Worst-case analysis

## Synchronous distributed algorithms

- If the nodes have unique identifiers, "everything" can be solved in diameter $(G)+1$ rounds
- Algorithm: each node

1. gathers full information about $G$ (including all local inputs)
2. solves the graph problem by brute force
3. chooses its local output accordingly

## Synchronous distributed algorithms

- If the nodes have unique identifiers, "everything" can be solved in diameter $(G)+1$ rounds
- Natural research problems:
- What can be solved in o(diam $(G))$ rounds?
- Focus: local algorithms
- What if we do not have unique identifiers?
- Focus: port-numbering model

## Model 1: Local algorithms

- An extreme version of sublinear-time algorithms: running time independent of the number of nodes
- Examples:
- running time 100 rounds in any graph
- running time $f(\Delta)$ in graphs with maximum degree $\leq \Delta$
- Our focus: deterministic local algorithms

## Deterministic local algorithms

- Running time is $T \Leftrightarrow$ output is a function of input within distance $T$
$T=2: \quad$ "Local neighbourhood"

## Deterministic local algorithms

- Scalability:
- Can be used in infinitely large (but locally finite) graphs
- Fault tolerance:
- Output can be re-computed repeatedly
- Efficient self-stabilising algorithm, recovers from any initial configuration, can be used in dynamic graphs
- Very limited model: what can be computed?

## Model 2:

## Port-numbering model

- No unique identifiers
- A node of degree d can refer to its neighbours by integers 1, 2, ..., d
- Port-numbering chosen by adversary
- Focus: deterministic algorithms

## Deterministic algorithms in the port-numbering model

- Graph + port numbering may be symmetric
- Nodes indistinguishable
- Identical inputs, deterministic computation, identical outputs
- Very limited model: what can be computed?

## Local algorithms and the port-numbering model

- Very limited models of distributed computing
- Local algorithms: constant time
- Port-numbering model: anonymous nodes
- Seemingly unrelated
- Why did I choose to introduce both?
- What can be said about these models?
- Certainly plenty of negative results, but do we have anything positive?

## Part II: Observations and results

- Similarities between local algorithms and the port-numbering model
- Case study: vertex cover problem
- Joint work with Matti Åstrand
- Examples of other positive results

## Local algorithms and the port-numbering model

- Orthogonal models
- All 4 combinations are reasonable
- All 4 combinations are distinct
- Simple (contrived) examples...

| Any running time |  |  |
| :---: | :--- | :--- |
| Local algorithms |  |  |
|  | Port numbering | Unique IDs |

## Local algorithms and the port-numbering model

- All 4 combinations are distinct
- Trivial problems can be solved in any model

| Any running time |  |  |
| :---: | :---: | :---: |
| Local algorithms | Constant function |  |
|  | Port numbering | Unique IDs |

## Local algorithms and the port-numbering model

- All 4 combinations are distinct
- Identifying all triangles (3-cycles):
- Local information is sufficient, but unique IDs are needed to distinguish between a cycle and a long path

| Any running time |  |  |
| :---: | :---: | :---: |
| Local algorithms | Constant function | Find triangles |
|  | Port numbering | Unique IDs |

## Local algorithms and the port-numbering model

- All 4 combinations are distinct
- 2-colouring edges of paths:
- Port numbering is sufficient, but the worst-case running time is necessarily $\theta(\operatorname{diam}(G))$

| Any running time | Path colouring |  |
| :---: | :---: | :---: |
| Local algorithms | Constant function | Find triangles |
|  | Port numbering | Unique IDs |

## Local algorithms and the port-numbering model

- All 4 combinations are distinct
- Spanning tree construction:
- Non-local problem
- Unique IDs needed to detect cycles

| Any running time | Path colouring | Spanning trees |
| :---: | :---: | :---: |
| Local algorithms | Constant function | Find triangles |
|  | Port numbering | Unique IDs |

## Local algorithms and the port-numbering model

- All 4 combinations are distinct
- However, there are surprising similarities between local algorithms and the port-numbering model
- Not fully understood yet!

| Any running time |  |  |
| :---: | :--- | :--- |
| Local algorithms |  |  |
|  | Port numbering | Unique IDs |

## Local algorithms and the port-numbering model

- There are problems where both models seem to be equally strong
- Best algorithm in port-numbering model is local
- Best local algorithm uses the port-numbering model

| Any running time |  |  |
| :---: | :--- | :--- |
| Local algorithms |  |  |
|  | Port numbering | Unique IDs |

## Local algorithms and the port-numbering model

- Example: minimum vertex cover
- Find a minimum-size subset $C$ of nodes that "covers" all edges: each edge incident to at least one node in $C$

- Classical NP-hard optimisation problem

| Any running time |  |  |
| :---: | :--- | :--- |
| Local algorithms |  |  |
|  | Port numbering | Unique IDs |

## Local algorithms and the port-numbering model

- Example: minimum vertex cover
- Best possible approximation ratio?
- Focus on bounded-degree graphs

| Any running time |  |  |
| :---: | :--- | :--- |
| Local algorithms |  |  |
|  | Port numbering | Unique IDs |

## Local algorithms and the port-numbering model

- Example: minimum vertex cover
- Trivial lower bound
- Cycles, optimum n/2
- Solution with < $n$ nodes requires symmetry-breaking

| Any running time | $\geq 2$ |  |
| :--- | :--- | :--- |
| Local algorithms |  |  |
|  | Port numbering | Unique IDs |

## Local algorithms and the port-numbering model

- Example: minimum vertex cover
- Non-trivial lower bound
- Cycles
- Czygrinow et al. 2008, Lenzen \& Wattenhofer 2008

| Any running time | $\geq 2$ |  |
| :---: | :---: | :---: |
| Local algorithms |  |  |
|  | Port numbering | Unique IDs |

## Local algorithms and the port-numbering model

- Example: minimum vertex cover
- Matching positive result
- Bounded-degree graphs
- One algorithm for both models

| Any running time | $\geq 2$ |  |
| :---: | :---: | :---: |
| Local algorithms | $\leq 2$ | $\geq 2$ |
|  | Port numbering | Unique IDs |

## Local algorithms and the port-numbering model

- Example: minimum vertex cover
- Best possible approximation ratios in bounded-degree graphs

| Any running time | 2 | 1 |
| :---: | :---: | :---: |
| Local algorithms | 2 | 2 |
|  | Port numbering | Unique IDs |

## Local algorithms and the port-numbering model

- Naturally, we can study running time with a finer granularity than $O(1)$ vs. arbitrary...
- However, anything larger-than-constant seems to lead to a very different model

| Any running time |  |  |
| :---: | :--- | :--- |
| Local algorithms |  |  |
|  | Port numbering | Unique IDs |

## Local algorithms and the port-numbering model

- Slightly non-constant running time together with unique IDs already makes a huge difference

## Local algorithms and the port-numbering model

- Slightly non-constant running time together with unique IDs already makes a huge difference

| $O(n)$ | Deterministic symmetry breaking in cycles |  |
| :---: | :---: | :---: |
| $O(\log n)$ |  |  |
| $O\left(\log ^{*} n\right)$ | Negative result | Cole-Vishkin 1986 |
| O(1) |  | Linial 1992 |
|  | Port numbering | Unique IDs |

## Local algorithms and the port-numbering model

- E.g., vertex cover in cycles becomes easier to approximate

| $O(n)$ | 2 |  |
| :---: | :---: | :---: |
| $O(\log n)$ | 2 | Greedy |
| $O\left(\log ^{*} n\right)$ | 2 | $\leq 4 / 3$ |
| $O(1)$ | 2 | 2 |
|  | Port numbering | Unique IDs |

## Local algorithms and the port-numbering model

- E.g., vertex cover in cycles becomes much easier to approximate

| $O(n)$ | 2 |  |
| :---: | :---: | :---: |
| $O(\log n)$ | 2 | Clustering |
| $O\left(\log ^{*} n\right)$ | 2 | $\leq 1+\varepsilon$ |
| $O(1)$ | 2 | 2 |
|  | Port numbering | Unique IDs |

## Local algorithms and the port-numbering model

- Hence the focus: strictly constant time and/or anonymous nodes

## Case study: <br> 2-approximation of vertex cover

- Lower bound result (for cycles):
- There is no local algorithm with approximation factor $2-\varepsilon$ for any $\varepsilon>0$
- I'll sketch Czygrinow et al.'s (2008) proof, which is a nice application of Ramsey's theorem
- Fast local algorithm (for bounded-degree graphs):
- 2-approximation in $O(\Delta)$ time in unweighted graphs
- Uses LP duality; finds a maximal dual solution using a combination of greedy increments and graph colouring

## Lower-bound result for vertex cover approximation

- Numbered directed $n$-cycle:
- directed $n$-cycle, each node has outdegree $=$ indegree $=1$
- node identifiers are a permutation of $\{1,2, \ldots, n\}$

## Lower-bound result for vertex cover approximation

- Fix any $\varepsilon>0$ and a deterministic local algorithm $A$
- Assumption: A finds a feasible vertex cover (at least in any numbered directed cycle)
- Theorem: For a sufficiently large $n$ there is a numbered directed $n$-cycle $C$ in which $A$ outputs a vertex cover with $\geq(1-\varepsilon) n$ nodes
- Corollary: Approximation ratio of $A$ is at least $2-2 \varepsilon$

## Lower-bound result for vertex cover approximation

- Let $T$ be the running time of $A$, let $k=2 T+1$
- The output of a node is a function $f$ ' of a sequence of $k$ integers (unique IDs)

## Lower-bound result for vertex cover approximation

- Lets focus on increasing sequences of IDs
- Then the output of a node is a function $f$ of a set of $k$ integers
$k=5:$

$$
\text { output }=f(\{6,7,11,13,21\})
$$

## Lower-bound result for vertex cover approximation

- Hence we have assigned a colour $f(X) \in\{0,1\}$ to each $k$-subset $X \subset\{1,2, \ldots, n\}$
$k=5:$

$$
\text { output }=f(\{6,7,11,13,21\})
$$

## Lower-bound result for vertex cover approximation

- Hence we have assigned a colour $f(X) \in\{0,1\}$ to each $k$-subset $X \subset\{1,2, \ldots, n\}$
- Fix a large $m$ (depends on $k$ and $\varepsilon$ )
- Ramsey: If $n$ is sufficiently large, we can find an $m$-subset $A \subset\{1,2, \ldots, n\}$
s.t. all $k$-subset $X \subset A$ have the same colour

## Lower-bound result for vertex cover approximation

- That is, if the ID space is sufficiently large...

## Lower-bound result for vertex cover approximation

- That is, if the ID space is sufficiently large, we can find a monochromatic subset of $m$ IDs...

$$
\begin{aligned}
& f(\{2,3,6,7,11\})=f(\{2,3,6,7,13\})= \\
& f(\{2,3,6,7,21\})=f(\{2,3,6,11,13\})= \\
& \ldots=f(\{6,7,11,13,21\})
\end{aligned}
$$

## Lower-bound result for vertex cover approximation

- Construct a numbered directed cycle: monochromatic subset as consecutive nodes

## Lower-bound result for vertex cover approximation

- Construct a numbered directed cycle: monochromatic subset as consecutive nodes

## Lower-bound result for vertex cover approximation

- Construct a numbered directed cycle: monochromatic subset as consecutive nodes

## Lower-bound result for vertex cover approximation

- Hence there is an $n$-cycle with a chain of $m-2 T$ nodes that output 1

## Lower-bound result for vertex cover approximation

- Hence there is an $n$-cycle with a chain of $m-2 T$ nodes that output 1
- We can choose as large $m$ as we want
- Good, more "black" nodes that output 1
- However, $n$ increases rapidly if we increase $m$
- Bad, more "grey" nodes that might output 0
- Trick: choose "unnecessarily large" $n$ so that we can apply Ramsey's theorem repeatedly

## Lower-bound result for vertex cover approximation

- Huge ID space...

## Lower-bound result for vertex cover approximation

- Find a monochromatic subset of size m...

## Lower-bound result for vertex cover approximation

- Delete these IDs...

## Lower-bound result for vertex cover approximation

- Still sufficiently many IDs to apply Ramsey...

## Lower-bound result for vertex cover approximation

- Repeat...

## Lower-bound result for vertex cover approximation

- Repeat until stuck

## Lower-bound result for vertex cover approximation

- Several monochromatic subsets + some leftovers

## Lower-bound result for vertex cover approximation

## Lower-bound result for vertex cover approximation

- Thus $A$ outputs a vertex cover with $\geq(1-\varepsilon) n$ nodes

## Lower-bound result for vertex cover approximation

- Thus $A$ outputs a vertex cover with $\geq(1-\varepsilon) n$ nodes
- In the proof, $n$ is huge - and this is necessary
- Using an upper bound on Ramsey numbers, the same proof would give a negative result for $T=O\left(\log ^{*} n\right)$
- With $T=\Theta\left(\log ^{*} n\right)$, we could do better!
- We have seen that $(2-\varepsilon)$-approximation is not possible in time independent of $n$
- Now let's see how to find a 2-approximation

## Local 2-approximation algorithm for vertex cover

- Convenient to study a more general problem: minimum-weight vertex cover
- Minimum-cardinality vertex cover: all weights = 1

Notation:
$w(v)=$ weight of $v$

## Local 2-approximation algorithm for vertex cover: background

- Edge packing: weight $y(e) \geq 0$ for each edge $e$
- Packing constraint: for each node $v$, the total weight of edges incident to $v$ is at most $w(v)$

## Local 2-approximation algorithm for vertex cover: background

- Edge packing: weight $y(e) \geq 0$ for each edge $e$
- Packing constraint: for each node $v$, the total weight of edges incident to $v$ is at most $w(v)$

## Local 2-approximation algorithm for vertex cover: background

- In linear programming, these are dual problems:
- minimum-weight (fractional) vertex cover
- maximum-weight edge packing

## Local 2-approximation algorithm for vertex cover: background

- Saturated node $v$ : the total weight on edges incident to $v$ is equal to $w(v)$

## Local 2-approximation algorithm for vertex cover: background

- Saturated edge $e$ : at least one endpoint of $e$ is saturated $\Leftrightarrow$ edge weight $y(e)$ can't be increased

## Local 2-approximation algorithm for vertex cover: background

- Maximal edge packing: all edges saturated $\Leftrightarrow$ none of the edge weights $y(e)$ can be increased $\Leftrightarrow$ saturated nodes form a vertex cover

## Local 2-approximation algorithm for vertex cover: background

- Minimum-weight vertex cover $C^{*}$ difficult to find:
- Centralised setting: NP-hard
- Distributed setting: integer problem, symmetry-breaking issues
- Maximal edge packing y easy to find:
- Centralised setting: trivial greedy algorithm
- Distributed setting: linear problem, no symmetry-breaking issues (?)

## Local 2-approximation algorithm for vertex cover: background

- Minimum-weight vertex cover $C^{*}$ difficult to find
- Maximal edge packing y easy to find?
- Saturated nodes $C(y)$ in $y$ : 2-approximation of $C^{*}$
- $w(C(y)) \leq 2 w\left(C^{*}\right)$
- Notation: $w(C)=$ total weight of the nodes $v \in C$
- Proof: LP-duality, relaxed complementary slackness

## Local 2-approximation algorithm for vertex cover: background

- Minimum-weight vertex cover $C^{*}$ difficult to find
- Maximal edge packing y easy to find?
- Saturated nodes $C(y)$ in $y$ : 2-approximation of $C^{*}$
- $w(C(y)) \leq 2 w\left(C^{*}\right)$
- Constant 2: $C(y)$ covers edges at most twice, $C^{*}$ at least once
- Immediate generalisation to hypergraphs
$w(C(y))=\sum_{v \in C(y)} y[v]=\sum_{e \in E} y(e)|e \cap C(y)| \leq 2 \sum_{e \in E} y(e)\left|e \cap C^{*}\right|=2 \sum_{v \in C^{*}} y[v] \leq 2 w\left(C^{*}\right)$

## Local 2-approximation algorithm for vertex cover

- Finding a maximal edge packing?
- Basic idea from Khuller et al. (1994) and Papadimitriou and Yannakakis (1993)

## Local 2-approximation algorithm for vertex cover: basic idea

- $y[v]=$ total weight of edges incident to node $v$
- Residual capacity of node $v: r(v)=w(v)-y[v]$
- Saturated node:
$r(v)=0$

## Local 2-approximation algorithm for vertex cover: basic idea

Start with a trivial edge packing $y(e)=0$

## Local 2-approximation algorithm for vertex cover: basic idea

Each node $v$ offers $r(v) / \operatorname{deg}(v)$ units to each incident edge

## Local 2-approximation algorithm for vertex cover: basic idea

Each edge accepts the smallest of the 2 offers it received

Increase $y(e)$ by this amount

- Safe, can't violate packing constraints

## Local 2-approximation algorithm for vertex cover: basic idea

Update residuals...

## Local 2-approximation algorithm for vertex cover: basic idea

Update residuals, discard saturated nodes and edges...

## Local 2-approximation algorithm for vertex cover: basic idea

Update residuals, discard saturated nodes and edges, repeat... Offers...

## Local 2-approximation algorithm for vertex cover: basic idea

Update residuals, discard saturated nodes and edges, repeat...
Offers...
Increase weights...

## Local 2-approximation algorithm for vertex cover: basic idea

Update residuals, discard saturated nodes and edges, repeat... Offers...

Increase weights... Update residuals...

## Local 2-approximation algorithm for vertex cover: basic idea

Update residuals, discard saturated nodes and edges, repeat...
Offers...
Increase weights...
Update residuals and graph, etc.

## Local 2-approximation algorithm for vertex cover: basic idea

This is a simple deterministic distributed algorithm
We are making some progress towards finding a maximal edge packing - but...

## Local 2-approximation algorithm for vertex cover: basic idea

This is a simple deterministic distributed algorithm
We are making some progress towards finding a maximal edge packing - but this is too slow!

## Local 2-approximation algorithm for vertex cover

- Offer is a local minimum:
- Node will be saturated
- And all edges incident to it will be saturated as well

## Local 2-approximation algorithm for vertex cover

- Offer is a local minimum:
- Node will be saturated
- Otherwise there is a neighbour with a different offer:
- Interpret the offer sequences as colours
- Nodes $u$ and $v$ have different colours: $\{u, v\}$ is multicoloured

## Local 2-approximation algorithm for vertex cover

- Progress guaranteed:
- On each iteration, for each node, at least one incident edge becomes saturated or multicoloured
- Such edges are be discarded; maximum degree $\Delta$ decreases by at least one
- Hence in $\Delta$ rounds all edges are saturated or multicoloured

## Local 2-approximation algorithm for vertex cover

- In $\Delta$ rounds all edges are saturated or multicoloured
- Saturated edges are good we're trying to construct a maximal edge packing
- Why are the multicoloured edges useful?

## Local 2-approximation algorithm for vertex cover

- In $\Delta$ rounds all edges are saturated or multicoloured
- Saturated edges are good we're trying to construct a maximal edge packing
- Why are the multicoloured edges useful?
- Let's focus on unsaturated nodes and edges

## Local 2-approximation algorithm for vertex cover: multicoloured edges

- Colours are sequences of $\Delta$ rational numbers
- Assume that node weights are integers 1, 2, ..., W
- Then colours are rationals of the form $q /(\Delta!)^{\Delta}$ with $q \in\{1,2, \ldots, W\}$

$$
(2,2 / 3,1 / 6,1 / 12)
$$

$$
(2,2 / 3,1 / 6,1 / 24)
$$

## Local 2-approximation algorithm for vertex cover: multicoloured edges

- Colours are sequences of $\Delta$ rational numbers
- Assume that node weights are integers 1, 2, ..., W
- Then colours are rationals of the form $q /(\Delta!)^{\Delta}$ with $q \in\{1,2, \ldots, W\}$
- $k=\left(W(\Delta!)^{\Delta}\right)^{\Delta}$ possible colours, replace with integers 1, 2, ..., $k$

## Local 2-approximation algorithm for vertex cover: multicoloured edges

- We have a proper $k$-colouring of the unsaturated subgraph
- Orient from lower to higher colour (acyclic directed graph)

## Local 2-approximation algorithm for vertex cover: multicoloured edges

- We have a proper $k$-colouring of the unsaturated subgraph
- Orient from lower to higher colour (acyclic directed graph)
- Partition in $\Delta$ forests
- Each node assigns its outgoing edges to different forests

## Local 2-approximation algorithm for vertex cover: multicoloured edges

- For each forest in parallel...

## Local 2-approximation algorithm for vertex cover: multicoloured edges

- For each forest in parallel:
- Use Cole-Vishkin (1986) style colour reduction algorithm
- Given a k-colouring, finds a 3-colouring in time $O\left(\log ^{*} k\right)$
- Bit manipulation trick: each step replaces a $k$-colouring with an $O(\log k)$-colouring

## Local 2-approximation algorithm for vertex cover: multicoloured edges

- For each forest and each colour $j=1,2,3$ in sequence:
- Saturate all outgoing edges of colour-j nodes
- Node-disjoint stars, easy to saturate in parallel
- In $O(\Delta)$ rounds we have saturated all edges

## Local 2-approximation algorithm for vertex cover: summary

- Total running time:
- All edges are saturated or multicoloured: $O(\Delta)$
- Multicoloured forests are 3-coloured: O(log* k)
- 3-coloured forests are saturated: $O(\Delta)$

- $O\left(\Delta+\log ^{*} k\right)=O\left(\Delta+\log ^{*} W\right)$
- $k$ is huge, but log* grows slowly

## Local 2-approximation algorithm for vertex cover: summary

- Maximal edge packing and 2-approximation of vertex cover in time $O\left(\Delta+\right.$ log* $\left.^{*} W\right)$
- $W=$ maximum node weight
- Unweighted graphs: running time simply $O(\Delta)$, independent of $n$
- Can be implemented in the port-numbering model

## Other examples of positive results

- Local algorithms for dominating sets: only trivial ( $\Delta+1$ )-approximation possible in general graphs
- However, there is an approximation scheme for fractional dominating sets
 (Kuhn et al. 2006)
- And constant-factor approximation algorithms for dominating sets in planar graphs
(Czygrinow et al. 2008, Lenzen et al. 2008)

## Other examples of positive results

- Edge dominating sets in the port-numbering model
- Best possible approximation ratios:

| Graph family |  | Approximation ratio |
| :---: | :--- | :--- |
| d-regular <br> graphs | $d=1,3, \ldots$ | $4-6 /(d+1)$ |
|  | $d=2,4, \ldots$ | $4-2 / d$ |
| graphs with <br> degree $\leq \Delta$ | $\Delta=3,5, \ldots$ | $4-2 /(\Delta-1)$ |
|  | $\Delta=2,4, \ldots$ | $4-2 / \Delta$ |

## Other examples of positive results

- Edge dominating sets in the port-numbering model
- Best possible approximation ratios:

Local algorithms!

| Graph family |  | Approximation ratio | Time |
| :---: | :--- | :--- | :--- |
| d-regular <br> graphs | $d=1,3, \ldots$ | $4-6 /(d+1)$ | $O\left(d^{2}\right)$ |
|  | $d=2,4, \ldots$ | $4-2 / d$ | $O(1)$ |
| graphs with <br> degree $\leq \Delta$ | $\Delta=3,5, \ldots$ | $4-2 /(\Delta-1)$ | $O\left(\Delta^{2}\right)$ |
|  | $\Delta=2,4, \ldots$ | $4-2 / \Delta$ | $O\left(\Delta^{2}\right)$ |

## Other examples of positive results

- Matchings in 2-coloured graphs, max degree $\leq \Delta$
- Time $\Omega(n)$ :
- maximum matching
- stable matching
- Time $f(\Delta, \varepsilon)$ :
- $(1+\varepsilon)$-approximation of maximum matching
- "almost stable" matching (fraction $\varepsilon$ of unstable edges)

## Other examples of positive results

- Matchings in 2-coloured graphs, max degree $\leq \Delta$
- Time $\Omega(n)$, even with unique IDs:
- maximum matching
- stable matching
- Time $f(\Delta, \varepsilon)$, in port-numbering model:

- (1 $+\varepsilon$ )-approximation of maximum matching
- "almost stable" matching (fraction $\varepsilon$ of unstable edges)

## Part III: Other models of computation

- Can we relate local algorithms to traditional complexity classes such as $\mathrm{NC}^{0}$ ?

## Distributed algorithms vs. traditional computational complexity

- Traditional view:
- Problem instance encoded as a string
- Distributed algorithms:
- Problem instance = structure of the system (graph)

## Distributed algorithms vs. traditional computational complexity

- Traditional view:
- Problem instance encoded as a string
- Can be interpreted as a path graph with local inputs
- Everything is a graph
- Let's study a simple model of computation...

## Distributed algorithms vs. traditional computational complexity

- Distributed algorithms on path graphs
- Constant-size local input
- Hence no unique IDs

## Local inputs

Local outputs

## Distributed algorithms vs. traditional computational complexity

- Deterministic local algorithms on path graphs
- Constant-size local input

(here $T=2$ )

## Distributed algorithms vs. traditional computational complexity

- Deterministic local algorithms on path graphs
- Constant-size local input

## Distributed algorithms vs. traditional computational complexity

- Deterministic local algorithms on path graphs
- Constant-size local input

Ridiculously restrictive model -
let's consider two different extensions...

Non-local connections, different circuits: $\mathrm{NC}^{0}$

General graphs:
local algorithms

## Distributed algorithms vs. traditional computational complexity

- $\mathrm{NC}^{0}$
- Deterministic local algorithms, port numbering

## Distributed algorithms vs. traditional computational complexity

- $\mathrm{NC}^{0}, \mathrm{NC}^{1}, \mathrm{NC}, \mathrm{RNC}, \ldots$
- Traditional computational complexity
- Deterministic local algorithms, port numbering
- Distributed algorithms

## Conclusions

- Local algorithms \& port-numbering model
- Non-trivial problems can be solved in very simple models of distributed computing
- Tight, unconditional lower bounds can be proven
- Research directions
- Better understand the similarities between the two models?
- Traditional computational complexity studies strings (= path graphs), consider more general graphs?
